A low-glycemic-load diet improves symptoms in acne vulgaris patients: a randomized controlled trial Abstract

A study by: Robyn N Smith, Neil J Mann, Anna Braue, Henna Mäkeläinen and George A. Varigos

Background:

Although the pathogenesis of acne is currently unknown, recent epidemiologic studies of non-Westernized populations suggest that dietary factors, including the glycemic load, may be involved.

Objective:

The objective was to determine whether a low-glycemic-load diet Results: improves acne lesion counts in young males.

Design:

15-25 y were recruited for a 12-wk, parallel design, dietary intervention incorporating investigator-blinded dermatology assessments. The experimental treatment was a low-25% energy from protein and 45%

tion emphasized carbohydrate-dense foods without reference to the glycemic index. Acne lesion counts and Conclusion: severity were assessed during monthly visits, and insulin sensitivity (using the homeostasis model assessment) was measured at baseline and 12 wk.

At 12 wk, mean (±SEM) total lesion counts had decreased more (P =0.03) in the low-glycemic-load group (-23.5 ± 3.9) than in the con-Forty-three male acne patients aged trol group (-12.0 ± 3.5). The experimental diet also resulted in a greater reduction in weight (-2.9 ± 0.8 compared with 0.5 ± 0.3 kg; P < 0.001) and body mass index (in kg/m2; - 0.92 ± 0.25 compared with 0.01 \pm glycemic-load diet composed of 0.11; P = 0.001) and a greater improvement in insulin sensitivity (from low-glycemic-index carbohy- 0.22 ± 0.12 compared with 0.47 \pm

drates. In contrast, the control situa- 0.31; P = 0.026) than did the control diet.

The improvement in acne and insulin sensitivity after a low-glycemicload diet suggests that nutritionrelated lifestyle factors may play a role in the pathogenesis of acne. However, further studies are needed to isolate the independent effects of weight loss and dietary intervention and to further elucidate the underlying pathophysiologic mechanisms.
